# MATHEMATICS – S3 Statistics

FRIDAY, 23 JUNE 2017 – MORNING

1 hour 30 minutes

## ADDITIONAL MATERIALS

In addition to this examination paper, you will need:

- a WJEC pink 16-page answer booklet;
- a Formula Booklet;
- a calculator;
- statistical tables (Murdoch and Barnes or RND/WJEC Publications).

## INSTRUCTIONS TO CANDIDATES

Use black ink or black ball-point pen.

Answer all questions.

Sufficient working must be shown to demonstrate the mathematical method employed.

#### **INFORMATION FOR CANDIDATES**

The number of marks is given in brackets at the end of each question or part-question. You are reminded of the necessity for good English and orderly presentation in your answers. 1. The weights, X grams, of the eggs sold in a certain farm shop have mean  $\mu$  grams. To estimate  $\mu$ , a random sample of 100 eggs was weighed, in grams, and the following sample statistics were calculated.

$$\Sigma x = 5910, \ \Sigma x^2 = 349425$$

Calculate an approximate 99% confidence interval for  $\mu$ .

- 2. Each of three fair dice has its six faces numbered 1, 2, 3, 4, 5, 6 respectively. The three dice are thrown simultaneously and the score on each dice is defined as the number on the uppermost face. Let *X* denote the highest score on these three dice.
  - Show that (a)

$$P(X \le x) = \left(\frac{x}{6}\right)^3$$
 for  $x = 1, 2, 3, 4, 5, 6.$  [2]

- (b) Deduce an expression in terms of x for P(X = x), valid for x = 1, 2, 3, 4, 5, 6. [2]
- Determine the most likely value of X. (C)
- 3. A zoologist claims that the mean weight of male dogs of a certain breed is 5 kg more than the mean weight of female dogs of the breed. Mair believes that the difference in mean weights is greater than 5 kg. She therefore collects and weighs random samples of 50 male and 50 female dogs of the breed. She defines the following hypotheses,

$$H_0: \mu_x - \mu_v = 5; \quad H_1: \mu_x - \mu_v > 5$$

where  $\mu_x$ ,  $\mu_y$  denote respectively the mean weights, in kg, of the male dogs and female dogs of the breed. The results are summarised below, where x, y denote respectively the weights, in kg, of the male dogs and the female dogs.

$$\sum x = 2055, \ \sum x^2 = 84773, \ \sum y = 1745, \ \sum y^2 = 61121$$

Determine an approximate *p*-value for these results and state your conclusion in context. [11]

- 4. A mathematics teacher takes a biased dice to his class, wishing to estimate p, the probability of throwing a 'six'. He throws it 75 times and obtains 24 'sixes'.
  - Calculate an approximate 95% confidence interval for *p*. (a)
  - The teacher calculates this interval and he asks Tom to interpret it. Tom states that 'There (b) is, approximately, a 0.95 probability that the interval that the teacher has calculated contains the unknown value of p'. Explain why this statement is incorrect and give a correct interpretation. [2]

[6]

[2]

[6]

5. When Dawn throws the javelin, the distance thrown (in metres) can be assumed to be normally distributed with mean  $\mu$  and variance  $\sigma^2$ . She throws the javelin 9 times with the following results.

- (a) Calculate unbiased estimates of  $\mu$  and  $\sigma^2$ . [5]
- (b) Calculate a 95% confidence interval for  $\mu$ .
- **6.** The length, *y* cm, of a spring subjected to a tension of *x* Newtons satisfies the relationship  $y = \alpha + \beta x$ , where  $\alpha$  and  $\beta$  are unknown constants. In order to estimate  $\alpha$  and  $\beta$ , the following measurements were made.

x	10	15	20	25	30	40
У	12.4	14.3	16·4	18·9	20.7	24.6

You are given that  $\sum x = 140$ ,  $\sum y = 107.3$ ,  $\sum x^2 = 3850$ ,  $\sum xy = 2744$ .

- (a) Calculate least squares estimates for  $\alpha$  and  $\beta$ , giving your answers correct to three significant figures. [6]
- (b) The values of x are exact but the values of y are subject to independent normally distributed measurement errors with mean zero and standard deviation 0.2. Before the measurements were made, Emlyn believed that the value of  $\beta$  was 0.4.
  - (i) State suitable hypotheses to carry out a two-sided test of Emlyn's belief.
  - (ii) Calculate the *p*-value of the above results.
  - (iii) State whether or not the data support Emlyn's belief.

# **TURN OVER**

[4]

[9]

7. An electronic device generates random digits from the set {1, 2, 3, 4}. The probability distribution of the digit generated, *X*, is given by

$$P(X = x) = \begin{cases} p & \text{for } x = 1\\ \frac{(1-p)}{3} & \text{for } x = 2, 3, 4 \end{cases}$$

where *p* is an unknown constant, 0 .

- (a) (i) Determine an expression for E(X) in terms of p.
  - (ii) Show that

$$Var(X) = \frac{2}{3}(1-p)(1+6p).$$
 [7]

- (b) In order to estimate p, a random sample of n digits is generated using the device and  $\overline{X}$  denotes the sample mean.
  - (i) Show that

$$U = \frac{3 - \overline{X}}{2}$$

is an unbiased estimator for p.

- (ii) Determine an expression for Var(U) in terms of *n* and *p*. [4]
- (c) The number of digits in the random sample equal to 1 is denoted by Y.
  - (i) Write down the distribution of *Y*.
  - (ii) Show that

$$V = \frac{Y}{n}$$

is an unbiased estimator for *p*.

(iii) Determine an expression for Var(V) in terms of n and p. [5]

(d) By considering 
$$\frac{Var(U)}{Var(V)}$$
, determine which is the better estimator, U or V. [4]

#### **END OF PAPER**
